Ad In AutoCAD, the model data are arranged in a file called a drawing. Drawings can be saved in many different file formats, such as DWG, DXF, PDF, or DWF. The file containing a drawing is called a drawing set. A drawing consists of vector objects and text (such as dimension and annotation). Vector objects are curves, lines, arcs, text, and other geometric shapes that appear in the drawing. Vector objects are created, edited, and viewed in a different drawing window. A person viewing the drawing must open the drawing in order to see the vector objects. If the viewer zooms into or out of the drawing, the vector objects can have a different appearance in different magnification views. The text in a drawing can be annotated and annotated with other text. An annotation is a note added to the drawing in order to make it easier to understand the drawing. The annotations can be notes to explain the layout or contents of the drawing. They can also be notes to specify or identify specific items in the drawing, such as a tag or text annotation. If the drawing has a floor plan, the plan can be viewed in perspective view. This helps a viewer understand the three-dimensional relationships between different drawing objects. The user interface for the drawing and vector objects is handled by the application programming interface (API). The API consists of commands and menus that the user enters with a keyboard or pointing device. The user typically types a letter or keystroke to access an item in the menu. In contrast, the drawing itself is the graphic that the user creates with a mouse or stylus. Ad The user interface for the text is handled by the application programming interface (API). AutoCAD can be used with hardware graphics tablets, often called digitizers, to allow users to draw on screen directly, without using a mouse. A graphics tablet converts the user's position and movements of the stylus into coordinates that are interpreted by the drawing. The first version of AutoCAD was released in December 1982. In 1984, Autodesk offered Autodesk Inventor, a 2D drafting and animation software application, for \$99 to allow users to make their own drawings and animations.

Some time ago I wrote a plugin to translate the templates from a resource file to a resx file. This is needed for localization of WPF applications. In this blog post I will describe how to use the plugin and how to do a build script in TeamCity which calls it. I use TeamCity to automate builds and to report build progress. For my application I use WPF and WPF templates to generate the UI from the resources. I had some problems with localization of WPF templates, which I solved by using a plugin to translate the templates from the resource file to the resx file. But my build process also generates the resource files so it is possible to build the application as well. I thought I would share this with other people and maybe help them with the following: I created a TeamCity build script which can be found in my github repository. The code is written in Java but it should be pretty easy to get the idea how it works. A Build Step The build script does two things: It generates resx files using a template file. It runs the generated resx files through a plugin to translate the template to resx. The build script runs the following: Generates a template file. Creates a new project and generates resx files. Adds the generated resx files to a file manager. Adds the resx file manager to the build process. Generate a Template File The template file contains the following code: #if (BuildConfig.Localize == "true") #region Translation #region Please use for the translation of this file #endregion #endregion #region Localize and Translate #region Please use for the translation of this file #endregion #endregion #region Translation #endregion This is the code for the template file which is generated by the build script:
